Simulated ASKAP-FLASH Data

Simulated ASKAP Data Cube

- 30 deg² field-of-view
- 2 hour integration
- 18 MHz bandwidth (vs full ASKAP 300 MHz)
- 1024 channels (vs full ASKAP 16 000)
- Continuum source catalogue from simulations by Wilman et al.(2008)

Gaussian HI 21 cm absorption components

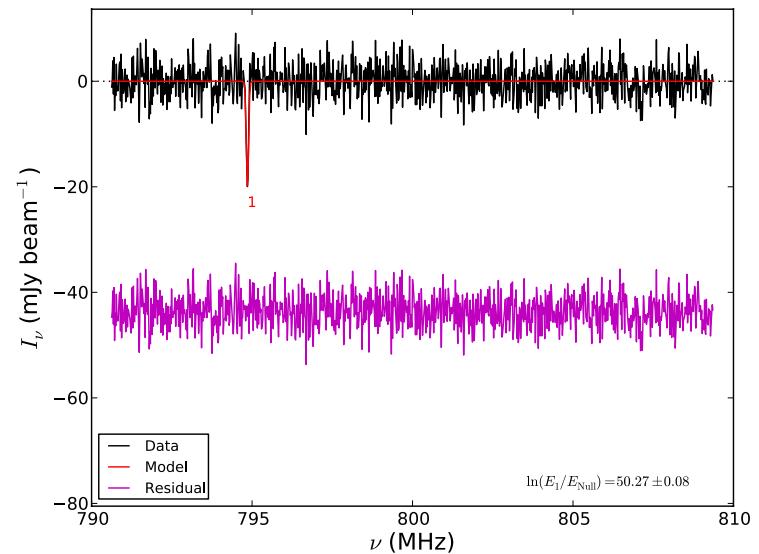

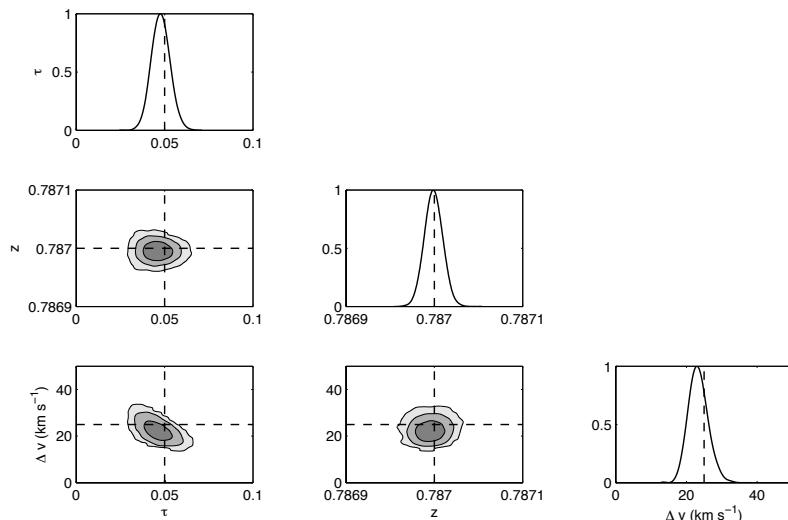

- 600 intervening absorption lines painted onto 435 brightest continuum sources ($S_{800} > 10$ mJy)
- Peak optical depths $0.01 < \tau < 0.30$
- Redshifts $0.760 < z < 0.792$ (793 – 807 MHz)
- Velocity widths $5 < \Delta v < 80$ km s⁻¹
- Spectra extracted at known source positions

Example Detection

1-dimensional line finding using Bayesian method

- Based on multi-nested sampling algorithm developed by Skilling (2004) and Feroz & Hobson (2008)
- Detection significance determined from ratio of evidence statistic for model with line vs no line
- Provides a quantitative measure of parameter probability and model suitability

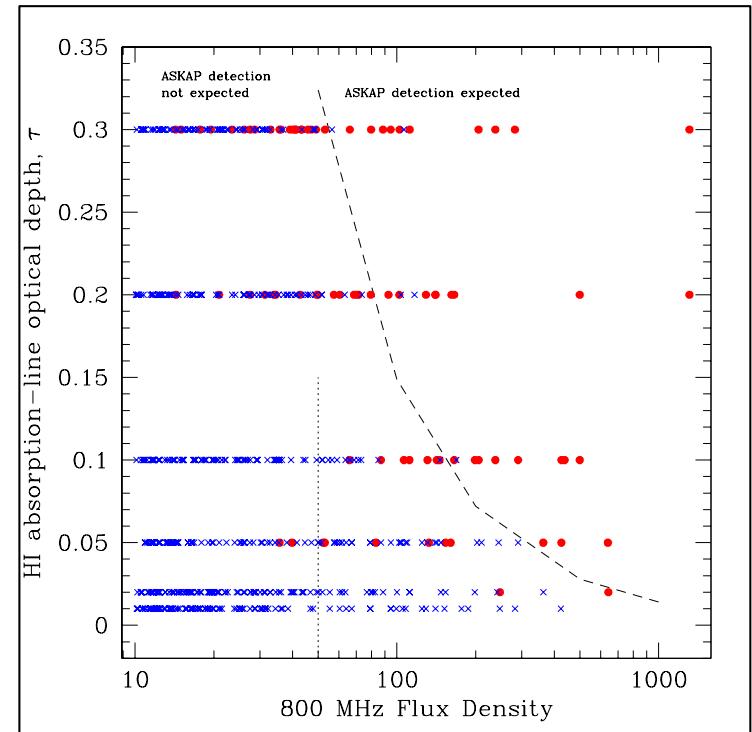

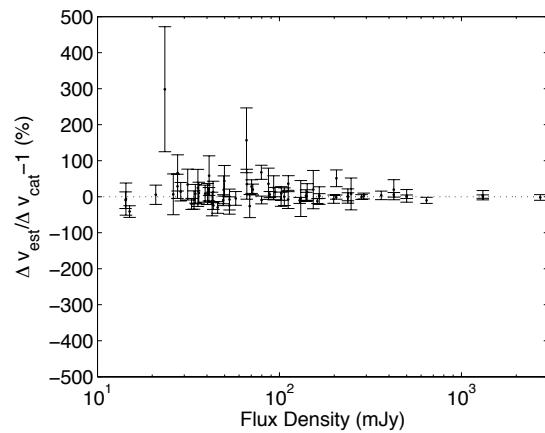

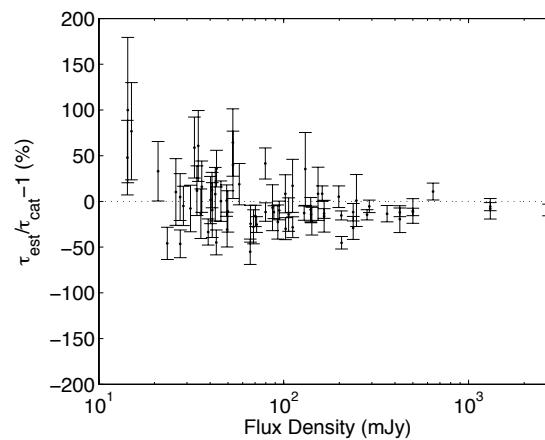

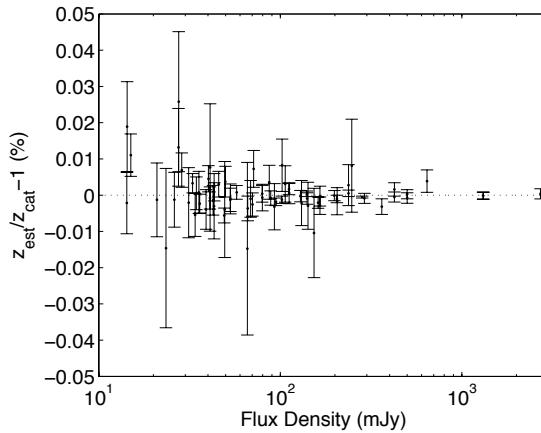

Example Detection

- Simulated ASKAP source of flux density $S_{800} = 198.7$ mJy
- Two input absorption line components present
- One component is detected with significance using a single Gaussian model
- Returned probability distributions for model parameters are consistent with input absorption-line catalogue values

Summary of detections in simulation

- Returned parameter values are consistent with input source catalogue
 - It is expected that FLASH will observe 150 000 continuum sources and return properties for over 1000 HI absorption systems

Expected ASKAP detections from 2hr pointing based on peak optical depth

- Red circle = Detection
- Blue cross = Non-detection
- Dashed line = Expected detection
